# Machine Learning Bagging and Boosting

#### S. Nõmm

<sup>1</sup>Department of Software Science, Tallinn University of Technology

18.04.2019

### Lectures and practices in May

- May the 2nd: Lecture as usual. Defend Home assignment 3 during the practice.
- May the 9th Closed book test 2. Practice is reserved for those who need to defend there home assignments 1, 2 and 3
- May the 16th. Make up tests during the lecture. Practice time is reserved for consultation.

### Bootstrap

- Remind what is the main goal of cross validation.
- Let  $Z=(z_1,\ldots,z_n)$  is the training set.
- Draw randomly data sets with replacement (the samples are independent) from Z. This will result in B bootstrap data sets.
- Fit the model for each of B data sets. Examine behaviour over B replacements.
- ullet This approach allows to estimate any aspect of distribution S(Z).

## **Bagging**

- Induced from the bootstrap technique (which is used to assess accuracy of estimate).
- Draw B samples with replacements and train the model on each sample.
- The bagging estimate then is defined by:

$$\hat{f}_{\text{bag}}(x) = \frac{1}{B} \sum_{b=1}^{B} \hat{f}^{*b}(x).$$

#### Random Forests

The idea is to build large collection of de-correlated trees, and then average them.

- For b=1 to B:
  - lacktriangleright Draw a bootstrap sample  $Z^*$  of size N from the available training data.
  - ▶ Grow tree *T<sub>b</sub>*. Repeat recursively for each terminal node until minimum node size is reached.
    - ★ Select m variables from p.
    - ★ Pick the best variable among m.
    - Split the node.
- Output the ensemble of trees  $\{T_b\}_1^B$ .
- Prediction:
  - Regression:  $\hat{f}_{\mathrm{rf}}^B(x) = \frac{1}{B} \sum_{b=1}^B T_b(x)$ .
  - ► Classification:  $\hat{C}_{rf}^B(x) = \text{mode}\{\hat{C}_b(x)\}_1^B$ .

## Committee learning

- Some times referred as ensemble learning.
- The idea is to combine a number of weak (accuracy is slightly larger than of random guessing) classifiers into a powerful committee.
- Motivation is to improve estimate by reducing variance and sometimes bias.

### **Boosting**

• The final prediction is given by:

$$G(x) = \operatorname{sign}\left(\sum_{m=1}^{M} \alpha_m G_m(x)\right).$$

which is weighted majority vote of classifiers  $G_m(x)$ . Here  $\alpha_m$  are weights describing contribution of each classifier.

- While on the first view result is very similar to the bagging, there are some major differences.
- Two class problem where output variable coded as  $Y \in \{-1, 1\}$ .
- For the classifier G(X) error rate is given by:

$$\overline{\text{err}} = \frac{1}{N} \sum_{i=1}^{N} I(y_i \neq G(x_i)),$$

where N is the power of training data set.

#### Ada Boost

AdaBoost.M1. by Freund and Shcapire (1997).

- Initialize observation weights  $w_i = 1/N$ , i = 1, ..., N.
- For m=1 to M:
  - Fit weak classifier  $G_m$  that minimizes the weighted sum error for misclassified points.

$$\epsilon_m = \frac{\sum_{i=1}^{N} w_i I(G_m(x_i) \neq y_i)}{\sum_{i=1}^{N} w_i}$$

- Compute  $\alpha_m = \log((1 \epsilon_m)/\epsilon_m)$ .
- ▶ Update weights  $w_i$  as

$$w_i = w_i * \exp(\alpha_m * I(y_i \neq G_m(x_i))), \quad i = 1, \dots, N.$$

Output classifier:

$$G(x) = \operatorname{sign}\left(\sum_{m=1}^{M} \alpha_m G_m(x)\right).$$
